Clear Out Console Script

```r
cat("\014")
```

So we have a bounded periodic function f and I'll assume the period is 2π, i.e. that
$f(x) = f(x + 2k\pi), -1 \leq f(x) \leq 1$ for all $k \in \mathbb{Z}, x \in \mathbb{R}$. We observe a scaled and shifted
realization: $y \sim Normal(f(\nu x + p), \sigma)$ and we want to determine ν, p.

We'll pick two arbitrary numbers x_1, x_2 as data. The only requirement is that those points are quite far
from each other, but are sorrounded by actually observed values. We'll parametrize our model in terms
of the value of the function at those points:

$$-1 < z_i < 1$$
$$z_1 = f(\nu x_1 + p)$$
$$z_2 = f(\nu x_2 + p)$$

The main advantage is that $z_1, z_2 \in (-1, 1)$ will almost always be well constrained by data, so no
multimodality problems here. But how do we get from z to ν, p?

We'll start by looking at preimages of z within a single period. We'll assume that each point has exactly
s distinct preimages in each period (some care would be needed to handle cases where some values
have more preimages than others, but it is IMHO possible). For the sin function $s = 2$ (we'll never have
exactly $z_i = \pm 1$).

$$0 \leq w_{i,j} < 2\pi$$
$$\{w_{1,1}, \ldots, w_{1,s}\} = f^{-1}(z_1)$$
$$\{w_{2,1}, \ldots, w_{2,s}\} = f^{-1}(z_2)$$

We then introduce additional parameter k that says how many full periods of the function are between
x_1 and x_2. So we have a set of pairs of preimages and we can use those to find all solutions for ν, p
given z.

**EDIT: ** There was previously a sign error in this equation.

$$\nu_{i,j,k} = \frac{w_{2,i} + 2k\pi - w_{1,j}}{x_2 - x_1}$$
$$p_{i,j,k} = w_{1,j} - \nu_{i,j,k} x_1$$

So beyond z_1, z_2 we need 3 discrete parameters: i, j, k. If we can put an upper bound on k (which we
IMHO always can as e.g. period shorter then distance between two consecutive points can be ruled
out), we can marginalize all the discrete parameters out! This way, we sum out all the modes. The
necessary background is at 7.2 Change point models | Stan User's Guide
